ABSTRACT

Introduction. Considered by many authors a vestigial structure, the appendix is a small dimensions organ with mostly unknown functions. Acute appendicitis is the most common condition of the ileocecal appendix, having multifaceted clinical manifestations, often masquerading as various unrelated syndromes, but causing increased morbidity, especially when diagnosed late. Although the disease could manifest at any age, there is a progressive increase of its incidence from birth, with a maximum between 10 to 40 years.

Case presentation. We report the case of an 84 years-old female patient, who presented with significant abdominal pain in the lower quadrants, mainly in the right iliac fossa and in whom the CT examination was suggestive of a utero-appendicular fistula, a very rare complication in daily practice and even more seldom encountered in the elderly.

Conclusions. Acute appendicitis remains a condition for which surgery is still the optimum treatment, especially in the case of an elderly patient having a radiologically suspected fistula with the uterus that could

RÉSUMÉ

Une complication rare d'appendicite aiguë – présentation de cas

Introduction. De petite dimension, avec un rôle presque inconnu, l'appendice est considéré un organe vestigial par beaucoup des auteurs. L'appendicite aiguë est la plus fréquente maladie de l'appendice iléocœcal ; elle constitue une urgence chirurgicale avec de multiples manifestations qui se superposent souvent sur d'autres syndromes avec une importante morbidité surtout si le diagnostic est retardé. Malgré le fait que la maladie peut survenir à tous les âges, une croissance progressive est constatée sur l'incidence à la naissance avec un pic entre 10 et 40 ans.

Rapport de cas. On va présenter le cas d'une patiente adressée au service de chirurgie ; Madame X, 84 ans, présente des douleurs dans l'étage abdominal inférieur et plus intenses dans la fosse iliaque droite. L'examen CT montre des images en faveur d'une fistule appendiculaire-utérine, une complication très rare au quotidien surtout pour les patients âgés.

easily lead to septic gynecological complications and possibly progression to multiple organ failure.

Keywords: appendicitis, fistula, diagnosis, appendicitis in the elderly.

INTRODUCTION

Acute appendicitis is one of the most frequent clinical situations which prompts urgent surgery and is more common in young patients, but also described in the elderly. Its diagnosis might be difficult in view of poor compliance in children and associated comorbidities in the ageing population. History and clinical examination are crucial in establishing the correct diagnosis in younger patients, whereas in the adult and the elderly population one requires additional investigations such as computed tomography in order to rule out the numerous differentials that can mimic acute appendicitis.

CASE PRESENTATION

We report the case of an 84 years-old female patient, from an urban area, who presented with moderate abdominal pain in the lower abdomen, especially in the right iliac fossa, which started approximately 2 weeks ago, has increased progressively and was not associated with nausea, vomiting or alteration of her bowel habits. Clinical examination revealed a moderately painful abdomen in the hypogastrium and the right iliac fossa, with guarding, but no rebound

Conclusions. L'appendicite aiguë reste l'une des maladies pour lesquelles la chirurgie est la meilleure solution de traitement, en particulier dans cette situation, dans le cas d'une patiente âgée, avec la suspicion d'une fistule impliquant l'utérus, un organe dont la pathologie infectieuse non traitée peut conduire relativement facilement à des complications graves SIRS / MSOF.

Mots-clés: appendicite, fistule, diagnostic, appendicite chez les personnes âgées.

tenderness or muscle contracture and no other relevant findings.

The blood tests results showed elevated WBC with neutrophilia and mild anemia, with no changes in the biochemistry and coagulation panels.

A computed tomography (CT) of the abdomen and the pelvis, with IV and oral contrast, demonstrated a significant enlargement of the uterine cavity filled with fluid, air and oral contrast (Fig. 1,2). The right lateral wall of the uterine cavity communicated through a broad, ill defined, fistulous tract, with the lower pole of the appendix (Fig. 3), suggesting that the fistula might be originating from an acutely inflamed appendix (Fig. 4).

We decided to proceed with urgent surgery through a pubio-umbilical median laparotomy. Intraoperatively, the uterus was enlarged, hyperemic, elastic, with a retro-uterine inflammatory mass incorporating the posterior wall of the uterus, the right adnexa, the cecum, portions of the small bowel and the sigmoid. After careful adhesion-lysis and release of the sigmoid colon and the small bowel, a fistulous tract was identified between the appendix and the uterine cavity, prompting total hysterectomy with bilateral adnexectomy and appendicectomy. Postoperatively, the patient was admitted to the Intensive Care Unit for

24 hours and had a favorable evolution, with rapid remission of the postoperative ileus and tolerance of food intake. On day 5 post-op, the patient had an accidental fall causing a left neck of femur fracture, for which she required left lower limb immobilization with a Dessault bandage.

DISCUSSION

Acute appendicitis continues to be the most common cause of surgical abdominal emergencies. It was often considered to be the disease of the young, but as a result of recent increases in lifetime expectancy, the incidence of acute appendicitis also increased in the elderly^{1,2}.

The positive diagnosis of acute appendicitis in younger patients is most often based on history and clinical examination, the imaging and laboratory results providing reassurance for the surgical team. In the elderly, such as in our case, because of associated comorbidities, the clinical picture might be silent and the incidence is much rarer, all these making a positive diagnosis more difficult, thus the need for supplementary investigations^{3,4}.

Delay in presentation was found by many authors to be the reason behind the higher rate of perforation seen in the elderly population^{1,2,5,6}.

CT scan was essential in establishing the diagnosis of acute appendicitis with utero-appendiceal fistula, reiterating the important role of imaging in the elderly patients, where one could encounter numerous differential diagnoses such as: acute diverticulitis with fistulous complications⁷, complicated Crohn's disease, cecum tumors, entero-uterine fistula, inflammatory or tumoral gynecological conditions, and various other causes of acute abdomen^{4,8-11}.

The surgical intervention could be performed either open or laparoscopically, but in this situation the

surgeon decided for a median laparotomy, in order to examine cautiously the whole peritoneal cavity and to eliminate a synchronous lesion and the mirage of the first lesion in a frail elderly patient¹²⁻¹⁴.

CONCLUSIONS

Acute appendicitis remains a condition for which surgery is still the optimum treatment, especially in the case of an elderly patient having a radiologically suspected fistula with the uterus that could lead easily to septic gynecological complications and possibly progression to MSOF.

Adequate postoperative care and nursing are of paramount importance even after the initial surgery especially in the elderly patients in whom complications occur easily and hinder favorable outcomes.
