ABSTRACT

Introduction. Pure white cell aplasia (PWCA) is a rare hematologic disorder characterized by the absence of neutrophil lineages in the bone marrow, with intact megakaryopoiesis and erythropoiesis. PWCA is commonly associated with several immune pathologies. Cytopenia in patients with thymoma is a paraneoplastic syndrome, along with other manifestations. The two major clinical issues in PWCA are various infectious complications and ulcerative-necrotic lesions of the skin and mucosa membranes.

Case presentation. We present a rare case of a patient with thymoma and PWCA, as paraneoplastic syndrome. On the background of agranulocytosis, the patient developed sepsis and infective endocarditis (IE) caused by a rare agent, carbapenem-resistant *Klebsiella pneumoniae*.

Conclusions. The rarity of endocarditis caused by *Klebsiella* species limits its recognition and awareness

RÉSUMÉ

Un cas rare d'aplasie pure des globules blancs chez un patient avec un thymome compliqué d'une endocardite infectieuse

Introduction. L'aplasie pure des globules blancs (PWCA) est une maladie hématologique rare caractérisée par l'absence de lignées de neutrophiles dans la moelle osseuse avec mégacaryopoïèse et érythropoïèse intactes. La PWCA est généralement associée à plusieurs pathologies immunitaires. La cytopénie chez les patients atteints de thymome est considérée comme l'une des maladies des syndromes paranéoplasiques avec d'autres manifestations. Les deux principaux problèmes cliniques de la PWCA sont diverses complications infectieuses et les lésions ulcéreuses-nécrotiques de la peau et des muqueuses.

Rapport de cas. Cet article décrit le cas rare d'un patient atteint de thymome et de l'un de ses syndromes

of its often severe course. Most cases of endocarditis with *Klebsiella pneumoniae* are associated with prosthetic heart valves. In patients with immunosuppression, such as PWCA associated with thymoma, and endocarditis, rare microorganisms must be considered.

Keywords: pure white cell aplasia, thymoma, infective endocarditis, neutropenia, agranulocytosis.

List of abbreviations:

AG – agranulocytosis
CT – computed tomography
CRP – C-reactive protein
ESBL – extended spectrum beta-lactamases
IE – infective endocarditis
PWCA – pure white cell aplasia
PNS – paraneoplastic syndromes

INTRODUCTION

Pure white cell aplasia (PWCA) is a rare hematologic disorder characterized by the absence of neutrophil lineages in the bone marrow, with intact megakaryopoiesis and erythropoiesis¹.

The main pathogenetic mechanism of PWCA is considered to be the immune-mediated suppression of granulopoiesis, with autoantibodies against the progenitor cells of granulocytes¹ and subsequent inhibition of granulocyte-macrophage colony-forming units². PWCA is commonly associated with several immune diseases (autoimmune hepatitis and primary biliary cirrhosis^{3,4}, autoimmune thyroiditis with autoantibodies to striated muscle cells and CD8⁺ naive

paranéoplasiques – une aplasie pure des globules blancs. Sur fond d'agranulocytose, il a développé une septicémie et une endocardite infectieuse, causée par un agent rare – *Klebsiella pneumoniae* résistant aux carbapénèmes.

Conclusions. La rareté de l'endocardite causée par l'espèce *Klebsiella* limite sa reconnaissance et la prise de conscience de son évolution souvent sévère. La plupart des cas d'endocardite à *Klebsiella pneumoniae* sont associés à des valves cardiaques prothétiques. Chez les patients présentant une immunosuppression, telle qu'une PWCA associée à un thymome et une endocardite, des micro-organismes rares doivent être pris en compte.

Mots-clés: aplasie pure des globules blancs, thymome, endocardite infectieuse, neutropénie, agranulocytose.

cells⁵). There have been described cases of recurrent PWCA after bone marrow transplantation, successfully treated with biological drugs⁶⁻⁹. Also, some of the reports described as “cases of agranulocytosis in patients with thymoma” may also be considered a manifestation of PWCA. This hypothesis may be confirmed by bone marrow histology (a pronounced decrease in the number of neutrophilic granulocytes), normal erythrocyte and platelet counts, and the history of treatment with immunosuppressive drugs (immunosuppressants, immunoglobulin drugs, cytostatics, genetically-engineered drugs)^{10,11}.

Cytopenia in patients with thymoma is considered a paraneoplastic syndrome¹², along with other manifestations¹³. The primary cause of paraneoplastic

Figure 1. Chest CT, soft tissue window (A,B). Large anterior mediastinal mass (arrows), 102x60x51 mm, with smooth contours, adjacent to the aorta and pulmonary trunk. Although it has a heterogeneous structure on the native CT, it demonstrated regular contrast enhancement.

syndromes in thymoma is dysregulation of thymus activity. Thymic epithelial cells have a lower expression profile of autoimmune regulator and major histocompatibility complex, and thymic architectonics becomes disrupted, leading to autoimmune complications¹⁴. Other causes of PWCA include viral infections, particularly parvovirus B19 infection¹⁵, and drugs¹⁶⁻¹⁸.

The two major clinical issues in PWCA are various infectious complications and ulcerative-necrotic lesions of the skin and mucosa membranes. It is essential to identify the correct cause of these complications and provide adequate therapy for both clinical manifestations and underlying neutropenia.

CASE PRESENTATION

A 68-year-old man was admitted to the hospital for fever, exertion dyspnea, and skin ulcers on the terminal phalanges of the 2nd and 3rd fingers of

both hands. He was hospitalized for the first time nine months before, with a presumptive diagnosis of pneumonia. On that time, an anterior mediastinal mass (Fig. 1) and pronounced neutropenia (up to 400 cells/L) were revealed.

The biopsy of the mass demonstrated a thymoma, type AB. The sternal puncture and trepanobiopsy did not confirm the assumption of a lymphoproliferative disease with bone marrow damage (Fig. 2).

As preoperative preparation, a recombinant human granulocyte colony-stimulating factor was prescribed, which successfully increased the number of neutrophils in the peripheral blood.

The patient was hospitalized in our hospital in a severe clinical state. Although there were no significant findings during the clinical examination, except for skin changes and basal crackles in both lungs, the blood tests demonstrated severe leukopenia (leukocytes $1.01 \times 10^9/L$) and neutropenia (neutrophils 4%, lymphocytes 76%, eosinophils 3%, monocytes

Figure 2. Tissue section of bone marrow. Fatty bone marrow prevails over the active. Erythropoiesis is represented by young forms. Granulocytopoiesis is markedly reduced, mature forms predominate. There are also single eosinophilic cells and megakaryocytes. **A.** H&E staining, x200. **B.** H&E staining, x400.

17%), mild anemia (hemoglobin 10.9 g/dL, erythrocytes $4.04 \times 10^{12}/L$), hyperglycemia (6.8 mmol/L), elevated total bilirubin (45.8 mmol/L) and lactate dehydrogenase (100 IU/L), and significantly increased C-reactive protein (270 mg/L).

The skin changes presented as painful black ulcers covered by scab, surrounded by hyperemia on the terminal phalanges of the thumbs, and pustular elements on the neck and forehead.

Chest computed tomography revealed infiltrative changes in basal lung segments, bilaterally, interpreted as bacterial pneumonia.

The microbiological examination of the secretion of pustulas and ulcers revealed contamination with *Staphylococcus aureus*, 10^5 CFU/mL, sensitive to ceftioxin and oxacillin.

The microbiological examination of the sputum was performed twice. Upon admission, *Escherichia coli* was detected, 10^6 CFU/mL, produced ESBL, sensitive to carbapenems, beta-lactams and tigecycline. On the 10th day of hospitalization, the examination revealed *Acinetobacter baumannii* 10^6 CFU/mL, sensitive only to polymyxin and tigecycline. The hemocultures, performed at the same time (on the 10th day of hospitalization), showed ESBL-producing *Klebsiella pneumoniae* and class D carbapenemase.

The esophagogastroduodenoscopy showed esophageal candidiasis, grade 2, ulcerative reflux esophagitis, superficial gastritis and duodenogastric reflux.

The echocardiography (Fig. 3) demonstrated dilatation of the ascending aorta and both atria and signs of the infective endocarditis. The aortic valve leaflets were thickened in the marginal zone, had loose structure due to vegetations, and there were signs of probable perforation of the non-coronary aortic valve leaflet.

For the first ten days, the patient was treated with meropenem 6 g/day, gentamicin 0.48 g/day and rifampicin 0.6 g/day for staphylococcal infection of the skin and soft tissues and bacterial pneumonia, and granulocyte colony-stimulating factor infusions. After the results of laboratory and instrumental investigations, the antibacterial therapy was adjusted: polymyxin B 200 mg/day + tigecycline 100 mg/day + meropenem 6 g/day. Moreover, antifungal treatment was initiated due to high risk of invasive candidiasis.

Despite the treatment, the patients' state continued to deteriorate, with worsening signs of heart failure, anemia and persistence of *Klebsiella pneumoniae* in blood cultures, and finally exitus.

DISCUSSION

The well-known manifestations of thymoma are various cytopenic syndromes, for example, partial red cell aplasia¹⁹. PWCA is a less known hematological

complication. In our patient, we assumed a relationship between thymoma and neutropenia. The severity of neutropenia in PWCA can be different, varying from a moderate decrease in the number of neutrophilic granulocytes to agranulocytosis, as in our patient. Neutropenia is referred as a number of neutrophils below $1.0 \times 10^9/L$ in children and $1.5 \times 10^9/L$ in adults, and agranulocytosis (AG) is considered at an absolute number of granulocytes below $500 \times 10^9/L$ ^{20,21}.

On the background of severe neutropenia, up to AG, the patient was diagnosed with sepsis with several primary foci – skin infection with multiple localization, bilateral pneumonia and infective endocarditis (IE). There are two distinct features of the infectious process in this clinical case: first, a rare incidence of IE in patients with AG, and, second, an unusual causative agent for IE, the nosocomial strain *Klebsiella pneumoniae* producing carbapenemase. IE is considered a rare infectious complication of neutropenia and AG.

Ljungman et al demonstrated that *Streptococcus viridans* and *Staphylococcus spp.* are the most common agents of sepsis in patients treated in the hematologic departments. Moreover, there was only one IE case, who met Duke criteria, among 66 documented cases with sepsis²². According to other authors, bacteremia in neutropenic patients receiving cytostatic chemotherapy is usually caused by *Streptococcus mitis* and *Streptococcus sanguis*, and IE in these patients is rarely observed (7-8% of cases)²³.

One of the reasons for the rare development of IE in neutropenic patients is the significant decrease or even loss of production of neutrophilic traps. Neutrophil extracellular traps induce vegetation formation through entrapping bacteria-platelet aggregates on the injured heart valves²⁴.

The risk factors for IE in our patient were ischemic heart disease, arrhythmias (paroxysms of atrial fibrillation), arterial hypertension, aortic valves alterations (thickening, induration, calcification) and the presence of other infectious foci (pneumonia, pyoderma).

It is worth noting the unusual etiologic agent of IE in our patient. The percentage of infection with *Klebsiella pneumoniae* in neutropenic patients reaches up to 10.8%²⁵, and IE cases have not been described in these patients. In addition, *Klebsiella pneumoniae* is regarded as a rare etiologic agent of IE, and each case of endocarditis of such etiology needs subsequent analysis, especially multidrug-resistant strains being isolated.

In one of the earliest reviews in 1999, Anderson & Janoff²⁶ analysed 48 cases of IE due to *Klebsiella pneumoniae*, described in the literature. The authors noted that IE extremely rarely complicates bacteremia with *Klebsiella pneumoniae*. In these cases, the results of antibiotic therapy are unsatisfactory, even in the case

of sensitive strains, and the mortality rate is about 49%. In another review, the authors also emphasized the rarity of IE cases caused by *Klebsiella pneumonia* and the high mortality, despite adequate antibiotic therapy, and noted that the early surgical treatment is associated with a better prognosis²⁷. Recently, a case of bacteremia with carbapenem-resistant *Klebsiella pneumonia* and IE was described in a patient after allogeneic bone marrow transplantation, with neutropenia²⁸. This patient received a combination of imipenem, sulbactam, gentamycin and tigecycline with a good evolution, being referred to surgery after the correction of AG. There are several cases in the literature with IE caused by *Klebsiella pneumonia* and *Klebsiella oxitoca* in intravenous drug addicted^{29,31} and hemodialysis patients³². Also, two cases of nosocomial IE in adults and children caused by ESBL-producing *Klebsiella pneumoniae* have been reported^{33,34}.

CONCLUSIONS

We reported a very rare case of IE in a patient with AG, caused by an atypical pathogen, nosocomial highly resistant *Klebsiella pneumoniae* strain that produces carbapenemase.

This case presents a collection of rarities in one particular patient. The patient was diagnosed with a relatively rare pathology (thymoma) and its equally rare complication, PWCA, with severe neutropenia, complicated by sepsis, with the development of soft tissue infection, pneumonia, and IE caused by a rare agent, carbapenem-resistant *Klebsiella pneumoniae*.

The rarity of endocarditis caused by *Klebsiella* species limits its recognition and awareness of its often severe course. Most cases of endocarditis with *Klebsiella pneumoniae* are associated with prosthetic heart valves. In patients with immunosuppression, such as PWCA associated with thymoma, and endocarditis, rare microorganisms must be considered.
